The most significant in Linux history occurred in 1991 when Linus Torvalds released the operating system. During this era , commercial operating system were expensive and forced businesses to develop custom software from scratch. Businesses needed reliable and affordable system to support websites, databases and other information systems. . Linux shined and dominated the server world . It Introduced a free and open-source operating system platform that allowed businesses to construct highly flexible information systems. Learning about the impact of Linux connects to my degree in Management Information System since it is a combination of business and technology. Linux existing was a game changer for the technology industry and I do not know what the world especially for businesses would be like without Linux.

I agree that Linux being released as open source was a major turning point because it allowed developers and users to see and work with the source code. I also think the shift from desktop computers to server infrastructure is especially important because it helped establish Linux as a foundation for modern computing. As someone interested in cloud administration and cybersecurity, I can see how that flexibility continues to make Linux valuable for managing systems.

I agree that the creation of Linux in 1991 was the most important event. You made a good point about how it changed things from 'closed black box' to being transparent. Being able to actually see and fix the code is a massive advantage for cyber security. It is way better than just waiting for a company to push out an update. The low level visibility tools we use would not be nearly as effective without that direct access to the kernel.
